

COMP 597: Assignment #1

Instructor: Xujie Si, TA: Breandan Considine

Due: Oct. 4th before class

This is the first assignment of COMP 597: Automated Reasoning with ML.

1 SAT Encoding

The following solutions can be obtained using a solver of your choice. Please show all work. Only solutions obtained using a SAT solver will receive credit.

Emirpimes (20 points): An *emirp* is a prime whose digits, when reversed, produce a different prime. An *emirpimes* is a semiprime whose reverse is a different semiprime, e.g., 50660299_{10} . Confirm its prime factors are emirps in bases 2 and 10. Find another such number. What is the largest emirpimes you can find, whose prime factors are distinct emirps in at least two bases?

Bonus (10 points): A *cryptarithm* is a cipher, $\varphi : \{A, \dots, Z\} \rightarrow \{0, \dots, 9\}$, alongside a meaningful string, whose ciphertext satisfies some equation, e.g.:

NINETEEN + THIRTEEN + THREE + TWO + TWO + ONE + ONE + ONE = FORTYTWO
42415114 + 56275114 + 56711 + 538 + 538 + 841 + 841 + 841 = 98750538

Construct a 20+-character cryptarithm parseable by the following grammar,

$$E \rightarrow A \mid \dots \mid Z \mid EE \mid EOE \mid (E)$$

$$O \rightarrow + \mid \times \mid \div \mid -^1$$

$$S \rightarrow E = E$$

where $\text{charset}(E) \neq \text{charset}(E')$ and $\text{eval}(\varphi(E)) = \text{eval}(\varphi(E'))$. Every plaintext word should be defined in the English 10k dictionary.² In order to receive credit, it must not be possible to find your cryptarithm (or algebraic rewritings thereof) on the internet or in other classmates assignments.

¹Interpreted in the usual way, but additive and multiplicative identity are forbidden.

2 Problem 2: Build or Improve a SAT Solver

Programming exercise (40 points): Please select one of the following two options, write a short report, and submit your source code. Please provide instructions for how reproduce your findings and a few test cases.

1. Write a SAT solver from scratch by implementing an existing algorithm such as DPLL, unit propagation or two-watched literals, describe your implementation and evaluate it on a few toy SAT problems.
2. Make a substantive improvement to a competitive SAT solver (e.g. Kissat or MiniSat) which measurably increases performance on a standard benchmark, and document your approach and findings.

3 Problem 3: Uninterpreted function equivalence

SMT exercise (40 points): Please typeset a proof sketch using L^AT_EX, then translate the proof into your favorite SMT solver to construct a specific example or counterexample. Show all work to receive full credit.

1. A polynomial equation whose coefficients and solutions are integers is called *diophantine*. Let $w, x, y, z \in \mathbb{Z}$ and report your solver's largest nontrivial solutions to each of the following diophantine equations:
(a) $w = x^3 + y^3 + z^3$ (b) $w^3 + x^3 = y^3 + z^3$ (c) $w^z + x^z = y^z + z$.
2. Prove that $\mathbb{Z}^{n \times n}$ is associative over \otimes , and \otimes is distributive over \oplus for some large n . **Bonus** (5 points): Give an example of a nontrivial finite commutative semiring whose elements are matrices and prove it.
3. A nonnegative matrix whose rows and columns all sum to the same number is called *bistochastic*. Find distinct examples $M_1, M_2 : \mathbb{Z}^{n \times n}$ for some large n such that both are nontrivial bistochastic matrices. **Bonus** (5 points): Is $M_i M_j$ is bistochastic for all bistochastic M_i, M_j ?
4. Consider the polynomial kernel $\Delta : (\mathbf{f}, \mathbf{g}) \mapsto (\mathbf{f} \cdot \mathbf{g} + r)^q$. The *kernel trick* states $\forall \mathbf{f}, \mathbf{g} : \mathbb{Z}^d, \exists \varphi \mid \langle \varphi(\mathbf{f}), \varphi(\mathbf{g}) \rangle = \Delta(\mathbf{f}, \mathbf{g})$. Show the kernel trick holds by finding φ for some large $r, d, q : \mathbb{N}$. What can we say about $\mathcal{O}(\langle \varphi, \varphi' \rangle)$ as $d, q \rightarrow \infty$? Is Δ a metric? Prove or disprove it.
5. Prove that 1D discrete convolution, $* : (f, g)[x] \mapsto \sum_{s \in S} f[x - s]g[s]$, over $S = [-j, j]$ for some large value $j \in \mathbb{N}$ is translation equivariant. **Bonus** (10 points): Prove the 2D case for MNIST, i.e., $[0, 255]^{28 \times 28}$.

Please submit your answers as a PDF and supplemental work as a ZIP file.
